Malformations in a Chornobyl-Impacted Region

WHAT’S KNOWN ON THIS SUBJECT: No other population-based birth defects surveillance data applying international standards concerning rates in Ukraine are known. Furthermore, no other reports on chronic low-dose ionizing radiation exposure population effects related to Chornobyl expressed as malformations are known.

WHAT THIS STUDY ADDS: Population-based rates of NTDs and other malformations in Ukraine that may reflect composite impacts of low-dose radiation, folate deficiencies, and prenatal alcohol teratogenesis are provided. This study provides a baseline for prospective investigations.

abstract

OBJECTIVE: One of the populations most exposed to chronic low-dose radiation from Chornobyl (Chernobyl in Russian) lives in Polissia, the region representing the northern half of Rivne Province (Oblast) in Ukraine. Here the patterns and population rates of malformations are reported and possible etiologic factors and regional contrasts are explored.

PATIENTS AND METHODS: Malformations, as defined by international standards, noted among all 96,438 births in Rivne between 2000 and 2006, were analyzed statistically. Contrasts of rates in Polissia compared with the rest of Rivne also were investigated.

RESULTS: The overall rate of neural tube defects in Rivne is among the highest in Europe (22.2 per 10,000 live births). The rates of conjoined twins and teratomas also seem to be elevated. In Polissia, the overall rates of neural tube defects are even higher (27.0 vs 18.3, respectively; odds ratio: 1.46 [95% confidence interval: 1.13–1.93]), and the rates of microcephaly and microphthalmia may also be elevated.

CONCLUSIONS: The malformation patterns observed suggest early disruptions of blastogenesis, manifesting as alterations of body axes, twinning, duplications, laterality, and midline formation. The results are sufficiently compelling to justify continuing and expanding this investigation of malformations in chronic low-dose radiation-impacted regions of Ukraine. Pediatrics 2010;125:e836–e843
In 1999, a Ukrainian population-based malformations surveillance system was established in Rivne and other provinces.1 The Rivne Province is located nearly 250 km west of the Chornobyl atomic power plants, and its northern half is a region known as Polissia. The Chornobyl explosion and fire started on April 26, 1986, and caused ionizing radiation-contamination across northwestern Ukraine. In Rivne, all Polissia counties (raions) were officially designated as significantly impacted (Fig 1). In addition, the Polissian radiation-contaminated soils have one of the highest known transfer rates of Cs$^{137}$ from soil to the food chain known in Ukraine.2 Recent radiation surveys confirmed that ingestion of Cs$^{137}$-contaminated foods, in particular milk and related products, is the main source of radiation exposures.3 Since recorded history, Polissia has been inhabited by “Polishchiks” (forest dwellers), whose culture has characteristics in common with those of other isolated populations. Most Polishchiks inhabit small villages and primarily subsist on homegrown vegetables, animal products, home-produced milk, and dietary supplements gathered in nearby forests (from wild berries and wild mushrooms, as well as by hunting and fishing). Polissia also extends to adjoining provinces in Ukraine and Belarus.

The current investigation was prompted by persisting public concerns about the impact of Chornobyl-related chronic radiation exposure on pregnancy outcomes and lack of population-based malformations data collected according to international standards. After 2 years of malformations monitoring, rates of neural tube defects (NTDs) including anencephaly, iniencephaly, rachischisis, spina bifida, and encephaloceles in Northwestern Ukraine (Volyn and Rivne provinces) were noted to be elevated.4 In addition, recurrent births of conjoined-twin sets were noted in Rivne, with none in 2 adjoining provinces (Volyn and Khmelnytsky).

The goal of this report is to present population rates of selected malformations noted during a 7-year period of standardized data collection and to compare and contrast these rates in the Polissian and non-Polissian regions of the Rivne Province. The specific malformations selected for comparison were NTDs; malformations related to twinning including conjoined twins, teratomas, and also microcephaly; and microphthalmia, all of which are malformations that may be due to prenatal exposure to ionizing radiation and the last two (microcephaly and microphthalmia) can also be due to prenatal exposure to alcohol.5

**PATIENTS AND METHODS**

In this report, the following conventions apply: "Rivne," unless specified otherwise, means Rivne Province, the capital of which is likewise named...
Rivne; Kostopil County represents a transition zone (the soils are characteristic of Polissia, but the inhabitants are not Polischuks); Kostopil is included in the non-Polissia category; and “rates in Europe” refer to those reported by the European Surveillance of Congenital Anomalies Organization (EUROCAT) for 2000–2006 (excluding instances because of chromosomal abnormalities). The malformation data presented were derived from virtually all 96 438 infants born in Rivne between 2000 and 2006, including from pregnancy terminations, pregnancy losses, stillbirths, and live births ascertained up to the age of 1 month. The methods used to ascertain and classify malformations conformed to the standards of the EUROCAT as described elsewhere. Infants with malformations are computed into a single category in a priority order reflected in data presentation. Data for infants with disorders of established etiology or pathogenesis are included in Table 1 and excluded from calculation of rates presented in Table 2. Microcephaly is defined as an occipitofrontal circumference at least 3 SDs below the norm for gestational age and gender of the infant using standard growth curves. Microcephaly is defined as an occipitofrontal circumference at least 3 SDs below the norm for gestational age and gender of the infant using standard growth curves.

Unique individuals (singleton, twin, or conjoined twins) of male, female, or unknown gender are included in the “total” categories. 

- Individuals with NTDs are computed first, followed by those with omphalocoele, those who are conjoined twins, teratomas, microcephaly, and microphthalmia, other concurrent malformations are described in the Appendix (cases a–x). Appendix is published as supplemental information at www.pediatrics.org/content/full/125/4/e836.
- Acrania and exencephaly are included.
- Inclusion of individuals who are a twin.
- Inclusion of individuals who are a member of a conjoined-twin set.
- Includes iniencephaly.
- Includes cervical or thoracic spinal schises.
- Includes spinal schises distal to the 11th thoracic vertebra.
- Instances likely to be due to mutations, chromosomal defects and exposures to alcohol.
- Includes gastrochisis.
- All were isolated sacrococcygeal teratomas.
- Includes anophthalmia and microphthalmia.
NTDs. The average rate in Europe was with at least 50 recorded instances of period in Europe by monitoring systems the rates reported during the same pe-

Polissia (27.0 vs 18.3) and higher than were significantly higher than in non-

Rivne and Volyn) reported for 2000 –2002.

The overall rate of NTDs in Rivne was nearly identical to the rate of 21 in Northwestern Ukraine (provinces of Rivne and Volyn) reported for 2000–2002. The overall NTD rates in Polissia were similar (86%) as were NTD subcategories. Early detection of NTDs (before the 28th week of gesta-
tion) was less frequent in Polissia (69%) compared with 77% in non-

crophthalmia and anophthalmia were merged into a single category, a dis-
tinction that otherwise would require autopsy studies. Statistical compar-
sions between specific malformation rates were made between Polissian

and non-Polissian regions by using \( \chi^2 \) or Fisher’s exact test as appropriate, and the unadjusted odds ratios (ORs) and the corresponding 95% confidence intervals (CIs) were calculated.

The proportions of isolated NTDs in Polissia versus non-

Polissia were similar (86%) as were

NTD subcategories. Early detection of

NTDs (before the 28th week of gesta-
tion) was less frequent in Polissia

(69%) compared with 77% in non-

Polissia (data not shown). The overall

NTD male/female ratio was 0.84 (Table

2). Among those of known gender, 5 of

6 of the conjoined-twin sets and 3 of 4

of those with teratomas were girls (Ta-

ble 1 and Appendix).

The association of NTDs with omphalo-
cles was noted in 9 of 217 (4.1%) indi-

viduals with NTDs compared with the

overall omphalocele rate of 0.04% (all

instances) or 0.015% (isolated in-

stances). There were 7 individuals

with an NTD-omphalocele association.

Among those of known gender, 4 of

6 were girls from Polissia, and 1 of 2 was

a boy from non-Polissia (Appendix). In

Europe, the omphalocele rates re-

ported by the EuroCAT during the

same period (based on at least 25 in-

stances) are similar (0.02%).

Concerning twinning, 6 of 217 individu-

als with NTDs were twins, and another

was a co-twin member of a craniortho-

cropulax set with a large lumbosa-

al spina bifida, and an omphalocele,

whereas her co-twin was malformation-

free (Table 1 and Appendix). In addi-

tion, there were 5 other conjoined-twin

sets (a thoracopagus set with 1 co-
twin with bilocular heart, 2 thoraco-

omphalopagi, and single instances of

craminothoracopagus and omphalopa-

gus sets). The Rivne rate of conjoined

twins was 0.62 compared with 0.18 in

Europe and 0.12 in the metropolitan At-

lanta area.57 The rates of conjoined

twins were similar in the Polissian and

non-Polissian areas, but the numbers

were very small. Regarding noncon-

joined twins, there were 757 pairs of

known gender. As shown in Table 3, 34

twins were malformed, and their co-
twins were malformation-free, 25 of

whom were of the same gender. There

were 6 twins with NTDs, 5 of the co-
twins were of the same gender, and all

were malformation-free. There were 7

sacroccocygeal teratomas for an over-

all rate in Rivne of 0.73, although pub-

lished rates have been within the

range of 0.25 to 0.50.6

As shown in Table 2, rates of micro-

cephaly and microphthalmia of un-

known etiology were 2.4 and 1.0,

respectively, and were significantly

higher in Polissia than in non-Polissia.
And a male with amniotic band syndrome, defect, a male with severe left uretherohydronephrosis, tricular septal defect, a female with an abdominal wall tricular septal defect, undefined cardiac malformation, Down syn- drome, and balanic hypospadia.

The third week after fertilization.

Rupt embryonal development before high prevalence of NTDs, probably fo-

Discussion

The risk factors in Rivne manifested as malformations include, among others, low-dose ionizing radiation, prenatal alcohol exposure, and, in view of the high prevalence of NTDs, probably folate deficiency. These factors can dis- rupt embryonal development before the third week after fertilization.

A report by the Committee on the Biological Effects of Ionizing Radiations, focused on health effects of low-level exposures, summarized prevalent views. Authors of the report noted that “the estimates of genetic risks in humans are based primarily on exper- imental data obtained with laboratory animals.” Authors of another report by the International Atomic Energy Agency, which coordinates United Na- tions and World Health Organization policies on Chornobyl health effects, asserted that “because of the relatively low doses to residents of con- taminated territories [in Ukraine, that there is] no evidence or likelihood [of detecting effects] . . . on the number of stillbirths, adverse pregnancy out- comes . . . or overall child health.” This position statement may have had a chilling effect on initiatives focused on investigations of malformation pat-

terns and rates in Chornobyl-impacted regions and may reflect a reliance on interpretations of data collected in Ja-

Pn by investigators sponsored by the Atomic Bomb Casualty Commission (ABCC). Other reports, also based on ABCC data, described the association of ionizing radiation exposure with microcephaly, and some of them have stressed that similar studies are de-

sirable in Chornobyl-impacted areas. Such recommendations were not in-

cluded among those endorsed by the International Atomic Energy Agency. However, several Chornobyl-related in-

vestigations have pointed toward its impact on human health and the ge-

nome. With respect to human malformations, 2 ABCC reports are of in-

terest. The first provided details of the methods and population studied, and the second report was focused on the array of malformations noted among children of nonconsanguineous parents, neither of whom were ex-

posed to significant doses of radiation. The aim of the investigation was to pro-

vide normative malformations data for Japan for comparison with other coun-

tries. The overall conclusion was that “the biological impact of congenital malformations is very similar in all

populations.” However, the report also noted that “the frequency of mal-

formed infants was significantly higher (P < .05) in Hiroshima and Na-

gasaki than in Kure (a control site). It should be noted that the array of malformations in Hiroshima-Nagasaki was similar to that in Rivne. Specifically, among 26,012 children from Hiro-

shima, 30,240 from Nagasaki, and 7,544 children from Kure, there were con-

joined twins (Hiroshima-Nagasaki, 1; Kure, 0), situs inversus (Hiroshima-

Nagasaki, 2; Kure, 0), teratoma (Hiroshima-Nagasaki, 3; Kure, 0), NTD (Hiroshima-Nagasaki, 46; Kure, 5), omphalocoele (Hiroshima-Nagasaki, 5; Kure 1), microcephaly (Hiroshima-

Nagasaki, 3; Kure, 0), anophthalmia (Hiroshima-Nagasaki, 15; Kure, 0), and atresia ani (Hiroshima-Nagasaki, 13; Kure, 0). Comparisons of low-dose ra-

diation exposures and dosimetry in Ja-

an and in Ukraine are complex; in Ja-

an exposures were acute and in Ukraine exposures are chronic.

With respect to Chornobyl, investigations in Belarus of pregnant women and new-

borns residing in the most severely im-

pacted regions by radiation suggested an increase in frequency of dicentric and ring chromosomes. Also noted was an increase in frequency of multiple con-

genital malformations and limb de-

fects. A comprehensive investigation of nearly half a million Swedish chil-

dren born between 1983 and 1988 demonstrated that those in utero ex-

posed at ~8 to 25 weeks of gestation during the Chornobyl accident had worse school outcomes than other birth cohorts. The impact was greatest in the 8 municipalities with the highest level of fallout. Such findings are con-

sonant with the view that the higher microcephaly rates noted in Polissia may also be because of chronic expo-

sures to ionizing radiation.

Two investigations focused on areas in proximity to atomic nuclear plants,
Hanford, California, and Sellafield, United Kingdom, are of interest. The first investigation found a significant association with NTDs, which was dismissed by the authors primarily because it contradicted conclusions based on ABCC data mentioned earlier.17 The second investigation showed a significant increased risk for still-births with congenital anomalies, in particular NTDs, most of which were anencephaly.18 Taking into account these and other similar investigations, the question of a low-dose radiation NTD association remains extant.19–21 In addition, the concurrent higher frequency of NTDs, microcephaly, and microphthalmia in Polissia, a region significantly exposed to low-dose radiation, is a finding sufficiently compelling to call for additional study.

Concerning the teratogenesis of alcohol, it is beyond dispute that prenatal exposures give rise to fetal alcohol spectrum disorders, which include microcephaly and microphthalmia. The relatively high proportion of microcephaly in combination with fetal alcohol spectrum disorders noted in Rivne underscores the importance for prospective investigations of microcephaly to include a focus on alcohol teratogenesis. Furthermore, high NTD rates in Rivne also suggest that folate deficiency may be prevalent, a factor that also may negatively affect DNA stability and repair, in a manner similar to exposures to low-dose radiation.22 To what extent synergistic effects of low-dose radiation, alcohol consumption, and folate deficiency are expressed in Rivne as NTDs, microcephaly-microphthalmia, and perhaps conjoined twins and teratomas remains unknown. However, the circumstances in Rivne are unique and favorable for concurrent investigations of these risk factors.

Regarding micronutrient deficiencies, apparently none of the population surveys in Ukraine focused on folates. On the other hand, worldwide experience shows that in a variety of areas with high NTD rates, folic acid consumption significantly reduces the occurrence of these malformations.23 Likewise, and irrespective of a micronutrient survey, programs to increase folic acid consumption in Rivne are expected to reduce NTD rates and should be implemented without delay. However, a nutrition survey in Rivne offers a unique opportunity to assess to what degree consumption of folic acid affects rates of NTDs and other malformations.

In Rivne, the NTD rates in Rivne are persistently elevated, and the rates of conjoined twins and sacrococcygeal teratomas, as noted in Rivne, can be viewed as forms of embryonal duplications.29,30 Early malformations in monozygotic twins and conjoined twins are more common and tend to affect only 1 member of the twin set.31 In Rivne, the concordance rate for malformations in like-gender co-twins is near 0. Studies of conjoined twins also showed that malformations preferentially affect the right-side co-twin, whereas the left co-twin was malformation-free.32 Hypothetically, the lack of concordance for malformations in twins may reflect alterations of “nodal flow” of extracellular fluid containing morphogens and regarded to be among the first left-right symmetry-breaking embryonal events.33,34 Also of interest are observations of left-isomerism sequence associated with maternal type 1 diabetes, also noted in insulin-dependent diabetes mellitus mouse models.35 Observations of monozygotic discordant twins with Wiedemann-Beckwith syndrome, preferentially in females, prompted the suggestion that a mechanism similar to X-chromosome inactivation may result in genomic imprinting, causing the malformation complex.36 In summary, additional investigations in Rivne concerning early malformations associated with twinning and female preference are indicated.

CONCLUSIONS

The NTD rates in Rivne are persistently elevated, and the rates of conjoined
twins and teratomas also seem to be elevated. The rates of NTDs in Polissia are higher than in non-Polissia, and rates for microcephaly and microphthalmia likewise seem to be elevated. The malformation patterns observed suggest early disruptions of blastogenesis, manifesting as alterations of body axes, twinning, sacrococcygeal teratomas, midline, laterality, and duplication anomalies with attention to gender preference. We admit that the limitations of this study include a lack of data regarding levels of low-dose radiation, consumption of micronutrients, degrees of consanguinity, and other data that may further define contrasts of Polissian and non-Polissian regions. However, these and other risk factors, including chronic low-dose radiation and alcohol effects on the unborn, can be clarified by concurrent prospective investigations. Existing local resources and the expressed interest by Rivne authorities to nurture partnerships with national and international teams will facilitate such initiatives.

ACKNOWLEDGMENTS

I thank the Rivne Oblast Public Health Administration, Regional Medical Diagnostic Center, and the OMNI-Net Work Group, including Victor Kovalyov, Ihor Shumlyanski, Lyubov Yevtushok, and Serhiy Lapchenko, for their assistance (Rivne Public Health Administration, Rivne, Ukraine). | m | 1 AN, TW, disc M-M. 2 AN, TW, disc M-M. |
| n | 1 CRA, abdominoschisis, unk. 2 CRA, esoph atr, F. 3 CRA, right multicystic kidney, F. 4 AN, esoph atr, F. 5 AN, acrania, CL/P, unk. |
| o | 1 L-SB, TW, disc F-F. 2 L-SB, TW, F disc F-M. |
| p | 1 L-SB, OM, CHD (hypopl L heart), M. 2 L-SB, OM, cong hydrocephalus, diaphr hernia, unk. 3 L-SB, diaphr hernia, anal atr, M. 4 L-SB, red legs, F. 5 L-SB, VSD, short L tibia, M. |
| q | 1 EN occipital, VSD, M. 2 EN frontal, amniotic bands, red limbs, unk. |
| r | 1 EN occipital, fam Meckel synd (related to r2), M. 2 EN occipital, fam Meckel synd (related to r1), unk. |
| s | 1 OM, post cranial fossa cyst, diaphr hernia, bilat clubhands, unk. 2 OM, Pentalogy of Cantrell, TW, disc M-amb. 3 OM, deformed lumbo-sacral spine and ankle joint, unk. 4 OM, CL/P bilat, postaxial polyd hands, single umbilical artery, F. |
| t | 1 OM, Patau synd (clindx), M. 2 OM, Beckwith Wiedemann synd, M. 3 OM, cong Ankyloblepharon, syndactyly 5-4 R fingers, M. 4 OM, cong cataract, glaucoma, hydrocephalus, CP, atr ext acoustic meatus, F. 5 OM, cong Ankyloblepharon, syndactyly 5-4 R fingers, M. 6 OM, cong cataract, glaucoma, hydrocephalus, CP, atr ext acoustic meatus, F. 7 OM, cong cataract, glaucoma, hydrocephalus, CP, atr ext acoustic meatus, F. |

### Microcephaly

| v | MIC, preaxial polyd, F. |
| w | 1 MIC, Seckel synd, M. |
| x | 1 MIC, Patau synd (clindx), M. 2 MIC, Down synd (clindx), F. 3 MIC, FAS, MOPHTH, M. 4 MIC, FAS, CP, F. |
| y | 1 MIC, FAS, ASD (ostium secundum), M. 2 MIC, FAS, VSD, ASD (ostium secundum, pulmonary sten), F. 3 MIC, FAS, VSD, M. |

### Microphthalmia–Anophthalmia

| z | MOPHTH bilat, VSD, M. |

Abbreviations: agen, agenesis; amb, ambigious genitalia; AN, anencephaly; apl, aplasia; ASD, atrial septal defect; atr, atriesia; bilat, bilateral; CHD, cardiac malformations; CL, cleft lip; clindx, clinical diagnosis, implies no karyotype; CL/P, cleft lip and/or palate; cong, congenital; CRA, cranioschisis; CTW, conjoined twins; diaphr, diaphragm; disc, discordant; diloc, dislocation; EN, encephalocele; esoph, esophagus; excl, excludes; ext, external; F, female; fam, familial; FAS, Fetal Alcohol syndr; H-SB, cervical—thoracic spina bifida, hydroceph, hydrocephalus; hypopl, hypoplasia; incl, includes; L, left; L-SB, lumbar—sacral spina bifida; M, male; MIC, microophthalmia; MOPHTH, microphthalmia or anophthalmia; mult, multiple; N, count of individuals; NTD, neural tube defects; OM, omphalocele; polyd, polydactyly; post, posterior; R, right; red, reduction; SB, spina bifida; sten, stenosis; synd, syndrome; TW, twins; unk, unknown gender; unilat, unilateral; VSD, ventricular septal defect.
